

Acxiom DS API August 2021 Release

Composite Endpoint Replacing Match

A new Composite Match Endpoint is taking the place of the Match Endpoint. Documentation on the Composite Match Endpoint is now available [here](#). The Composite Endpoint is an input interface that allows users to input a single record and is capable of returning data from multiple document types (e.g., person, place, entity, household, residency) in one response. Composite requests can be submitted as a single record or as a batch of records, each using a JSON POST request. The Composite Match Endpoint only returns attributes as defined in a user bundle.
